Abstract

We study the 2-flavor lattice Schwinger model with Wilson fermions in the chiral limit. The quark mass is determined using the PCAC definition. We numerically compute the masses of the iso-triplet (π) and iso-singlet particles (η) for different quark masses and compare our results with analytical formulas.

Introductory remarks

Although we begin to understand the formulation of chiral fermions on the lattice [1], the high cost of their simulation still renders Wilson fermions an attractive alternative. Wilson fermions, however, suffer from an explicit breaking of chiral symmetry and can only in a carefully taken chiral limit be used to analyze chiral aspects of QCD. Approaching and properly understanding this limit is a non-trivial task and studies in 2-dimensional models contribute to our understanding.

The Schwinger model [2] with two flavors is a particularly convenient testbed for studying the chiral limit since it shares several characteristic features with QCD. The low lying spectrum ("mesons") contains an iso-triplet of light particles (π's) which become massless in the chiral limit. In addition a massive iso-singlet state (η) appears, giving rise to a U(1) problem equivalent to QCD. For the massless case the analytical solution of the Schwinger model in the continuum has been known for many years and also for small fermion masses some analytical results for the model with flavor have become available [3]-[12].

For the lattice model with staggered fermions the connection to these continuum results is well understood [13]-[20]. The challenge in a lattice simulation with Wilson fermions is to properly fine-tune the bare parameters and drive the pions to zero mass. Although many aspects of the Schwinger model with Wilson fermions are well understood - in particular the relation between the spectrum of the Dirac operator and the topology of gauge fields [21]-[25] has been studied intensively - relatively little [26]-[29], [31] is known for the chiral limit with Wilson fermions. What is still lacking is a high precision numerical study of the mass spectrum for Wilson fermions combined with a systematic comparison to analytical results. Furthermore the Schwinger model allows for a simple implementation of the PCAC method [30] for defining the quark mass. Using this definition together with the numerical results for the mesons in the comparison to analytical formulas leads to an interesting test of the PCAC quark mass definition.

In this letter we report on our study of the two-flavor lattice Schwinger model with Wilson fermions. In particular we concentrate on the low-lying particle spectrum (π's, η) and the behavior in the chiral limit. We use the PCAC method to define the quark mass m and compare our results for the spectrum of the meson masses as a function of m with analytical formulas.

Setting, quark mass and observables

The action for the Schwinger model with Wilson fermions consists of two parts $S = S_G + S_F$ with S_G and S_F being the gauge field and fermion action (2 flavors) both in standard Wilson formulation. We work on $L \times L$ lattices with periodic boundary conditions for the gauge fields and mixed periodic boundary conditions (periodic in space-, anti-periodic in time-direction) for the fermions. We simulate the system on lattices of size $L = 16, L = 24$ and $L = 32$ and β-values of $\beta = 2, 4, 6$. For the smallest lattice we use 10^4 configurations for the determination of the observables, while for $L = 24$ and $L = 32$ we typically use 10^3 configurations but increase this number for some values of the parameters where better statistics is desirable. The update is done using the standard hybrid Monte Carlo method [32] with 10-steps trajectories and a step size adjusted such that the average acceptance rate is 0.8. Several observables, including the geometric topological charge, are monitored and appropriate numbers of configurations are discarded between the measurements to assure proper de-correlation and achieve topological ergodicity.

The quark mass is determined using the PCAC method as outlined in [30]. The essential idea is to use the coefficient of the right hand side of the axial SU(2) Ward identity as a definition of the mass. One computes the matrix elements with a pseudo-scalar source on both sides of the Ward identity and the quark mass is then given by the ratio of the vev.'s for the two sides. The details on the implementation of the method for the lattice Schwinger model were reported elsewhere [31]. Here we just briefly summarize the relevant formulas. The quark mass is defined as ($x \neq y$, $\mu = 1, 2$)

$$m \;=\; \frac{1}{2}\frac{\sum_\mu \left[\langle 0|\pi_y^{a\dagger} J_x^{5a\mu}|0\rangle - \langle 0|\pi_y^{a\dagger} J_{x-\mu}^{5a\mu}|0\rangle\right]}{\langle 0|\pi_y^{a\dagger}\pi_x^a|0\rangle}\;, \tag{1}$$

with

$$\begin{aligned} \pi_x^a &= \frac{1}{2}\overline{\psi}_x\, \tau^a \otimes \gamma_5\, \psi_x\;, \\ J_x^{5a\mu} &= \frac{1}{4}\Big[\overline{\psi}_{x+\hat{\mu}}\, U_{x,\mu}^\dagger\, \tau^a \otimes\; \gamma_\mu\gamma_5\, \psi_x \;+\; \overline{\psi}_x\, \tau^a \otimes \gamma_\mu\gamma_5\, U_{x,\mu}\, \psi_{x+\hat{\mu}}\Big]\;. \end{aligned} \tag{2}$$

The gamma matrices are chosen as $\gamma_1 = \sigma_1, \gamma_2 = \sigma_2$ and $\gamma_5 = \sigma_3$ with σ_j denoting the Pauli matrices. The generators τ^a of rotations in flavor space are also given by the Pauli matrices $\tau^a = \sigma_a,\ a = 1, 2, 3$. The quark mass m was computed for each β, L and κ individually.

The masses for the pions and the eta-particle were computed from the decay of two point functions of the following *currents*

$$\begin{aligned} J_x^{a\mu} &= \overline{\psi}_x \, \tau^a \otimes \gamma_\mu \, \psi_x \qquad \text{for the } \pi\text{'s} \, , \\ J_x^{0\mu} &= \overline{\psi}_x \, \mathbb{1} \otimes \gamma_\mu \, \psi_x \qquad \text{for the } \eta \, . \end{aligned} \tag{3}$$

We emphasize that 2-point functions of *scalars* or *pseudo-scalars* are not particularly well suited for the determination of the meson masses. These operators are bosonized (compare the discussion below) by cosines and sines of the fundamental fields [5, 8] and their 2-point functions strongly mix contributions from both the triplet and singlet states.

Finally let us briefly discuss the correspondence of the gauge coupling on the lattice to the gauge coupling g as it appears in the continuum formulas below. The Schwinger model is a super-renormalizable theory, i.e. the bare coupling does not get renormalized and equals the physical coupling g.

On the lattice we use the usual factor β in front of the gauge field action. In the naive continuum limit it is related to the continuum coupling g via (we set the lattice spacing $a = 1$)

$$\beta \; = \; \frac{1}{g^2} \; . \tag{4}$$

Again we can use the super-renormalizability of the model and define the coupling g which we use for comparison with the analytical results in the continuum (see below) through (4).

Analytical results for the continuum model

Before we start with the presentation of our numerical results, let us briefly discuss the known analytical results for the continuum model. This is best done by looking at the generalized Sine Gordon model which bosonizes the 2-flavor Schwinger model [4]. Its Lagrangian reads

$$\frac{1}{2}\Big(\partial\varphi^{(0)}\Big)^2 + \frac{1}{2}\Big(\partial\varphi^{(3)}\Big)^2 + \frac{1}{2}\,\frac{2\,g^2}{\pi}\Big(\varphi^{(0)}\Big)^2 - \frac{m\,c}{\pi}\cos\Big(\sqrt{2\pi}\,\varphi^{(0)}\Big)\cos\Big(\sqrt{2\pi}\,\varphi^{(3)}\Big) \; . \tag{5}$$

The constant c is not determined by the bosonization but is related (see e.g. [8, 10]) to the masses $\mu^{(0)}$ and $\mu^{(3)}$ used for normal ordering of the fields $\varphi^{(0)}$ and $\varphi^{(3)}$ by $c = (\mu^{(0)}\mu^{(3)})^{1/2}e^{\gamma}/2$, where γ denotes Euler's constant $\gamma = 0.577216\ldots$. For the case of two flavors two of the currents which we measure (compare (3)) are bosonized with the following prescription (here $\tau^0 \equiv \mathbb{1}$)

$$\overline{\psi}(x)\,\tau^a \otimes \gamma_\mu\,\psi(x) \;=\; \frac{1}{\sqrt{\pi}}\,\varepsilon_{\mu\nu}\,\partial_\nu\,\varphi^{(a)}(x) \quad , \qquad a = 0,3\;. \tag{6}$$

For the other two members $j_\mu^{(1)}, j_\mu^{(2)}$ of the iso-triplet no abelian bosonization is known. However since the original model is invariant under flavor rotations, their masses are the same as for the triplet current ($a = 3$, pions). When setting the quark mass m in (5) to zero, the two flavor Schwinger model is bosonized by two free fields. One of them, the pion field $\varphi^{(3)}$, is massless ($M_\pi = 0$) and the eta field $\varphi^{(0)}$ obtains the Schwinger mass $M_\eta = g\sqrt{2/\pi}$.

For non-vanishing quark mass, also the bosonized model (5) can no longer be solved in closed form. A first approach is to use a semi-classical analysis (see e.g. [10]) which gives a good approximation when all involved masses are large. One simply determines the minimum of the interaction part $V[\varphi^{(0)}, \varphi^{(3)}]$ of (5) and the squares of the masses are then given by the second derivatives of $V[\varphi^{(0)}, \varphi^{(3)}]$ at the minimum. After normal ordering the fields $\varphi^{(a)}$ with respect to their own masses (i.e. setting $\mu^{(0)} = M_\eta$ and $\mu^{(3)} = M_\pi$), the semi-classical analysis for the iso-triplet and iso-singlet gives

$$\frac{M_\pi}{g} \;=\; e^{2\gamma/3}\,\frac{2^{5/6}}{\pi^{1/6}}\left(\frac{m}{g}\right)^{2/3} \;=\; 2.1633\ldots\left(\frac{m}{g}\right)^{2/3} \quad , \tag{7}$$

and

$$\frac{M_\eta}{g} \;=\; \sqrt{\frac{2}{\pi} \;+\; \Big(\frac{M_\pi}{g}\Big)^2}\;. \tag{8}$$

We remark that the latter equation, i.e. the semi-classical relation between M_η and M_π, holds independently of any normal ordering prescription or the value of M_π, due to the formula $\partial^2/\partial{\varphi^{(0)}}^2 V = g^2 2/\pi + \partial^2/\partial{\varphi^{(3)}}^2 V$, which in turn is evident from (5). This will be explored below.

In an attempt to go beyond semi-classical analysis one can approximate the generalized Sine-Gordon model (5) by a solvable model. One possibility [4] is to analyze the model in the limit of large coupling g and small mass m where the iso-singlet field $\varphi^{(0)}$ becomes static and the model is reduced to a standard Sine-Gordon model for the triplet field $\varphi^{(3)}$

$$\frac{1}{2}\Big(\partial\varphi^{(3)}\Big)^2 \;-\; 2C\cos\Big(\sqrt{2\pi}\varphi^{(3)}\Big)\;. \tag{9}$$

This reduced bosonized theory has been studied [4, 15] using the WKB approximation [33] for (9). The spectrum of the model (9) contains a soliton, an anti-soliton and two soliton–anti-soliton bound-states. The lighter bound state has a mass equal to the soliton (and anti-soliton), and the mass for this triplet can be related to the mass of the iso-triplet in the 2-flavor Schwinger model. More recently (9) was studied again by Smilga [12] but his analysis is now based on the newly found analytic solution [34] of the standard Sine-Gordon model. Smilga finds

$$\frac{M_\pi}{g} \;=\; 2^{5/6}\, e^{\gamma/3} \left(\frac{\Gamma(\frac{3}{4})}{\Gamma(\frac{1}{4})}\right)^{2/3} \frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \left(\frac{m}{g}\right)^{2/3} \;=\; 2.008\ldots \left(\frac{m}{g}\right)^{2/3} \quad . \tag{10}$$

Obviously the truncation of the original model (5) to the standard form (9) does not allow for a result for the singlet mass M_η. For this state only the semi-classical formula (8) is available. It his however interesting to use the exact result (10) of the truncated model as an input in (8), and below we compare also this formula to the numerical data.

Numerical results

Let us now discuss our numerical results for the mass spectrum. We start with presenting the data for the triplet mass in Fig. 1 and compare them to the semi-classical-result (7) and Smilga's formula (10). We show our results for $\beta = 2, 4, 6$ in the first three plots and and in each plot combine all available values for the sizes L. In the last plot we zoom in on the chiral region of the $\beta = 4$ plot. We compare the numerical results to Smilga's formula (10) (full line) and the semi-classical result (7) (dotted line). We remark, that the errors in the determination of m from (1) are smaller than the symbols and thus no horizontal error bars were included in the plots.

It is obvious, that the approach to the chiral limit is under good control, i.e. the pion mass M_π vanishes as the PCAC quark mass goes to zero. In addition the data is well described by the analytical result (10) (full line). In particular at small quark mass and low β where Smilga's assumption $m \ll g$ is fulfilled best, the coincidence of the data with (10) is convincing. For increasing quark mass we observe a cross-over behavior and the data is then better described by the semi-classical result (7) which is represented by the dashed line. This deviation from (10) was also observed for staggered fermions in [18]. The comparison of the data at different lattice sizes L

shows, that the data points essentially fall on top of each other and for our parameters L and β the finite size effects are negligible. When zooming in on the very small m region (last plot in Fig. 1) the error bars become larger due to the small M_π, but the approach to the chiral limit is still relatively clean.

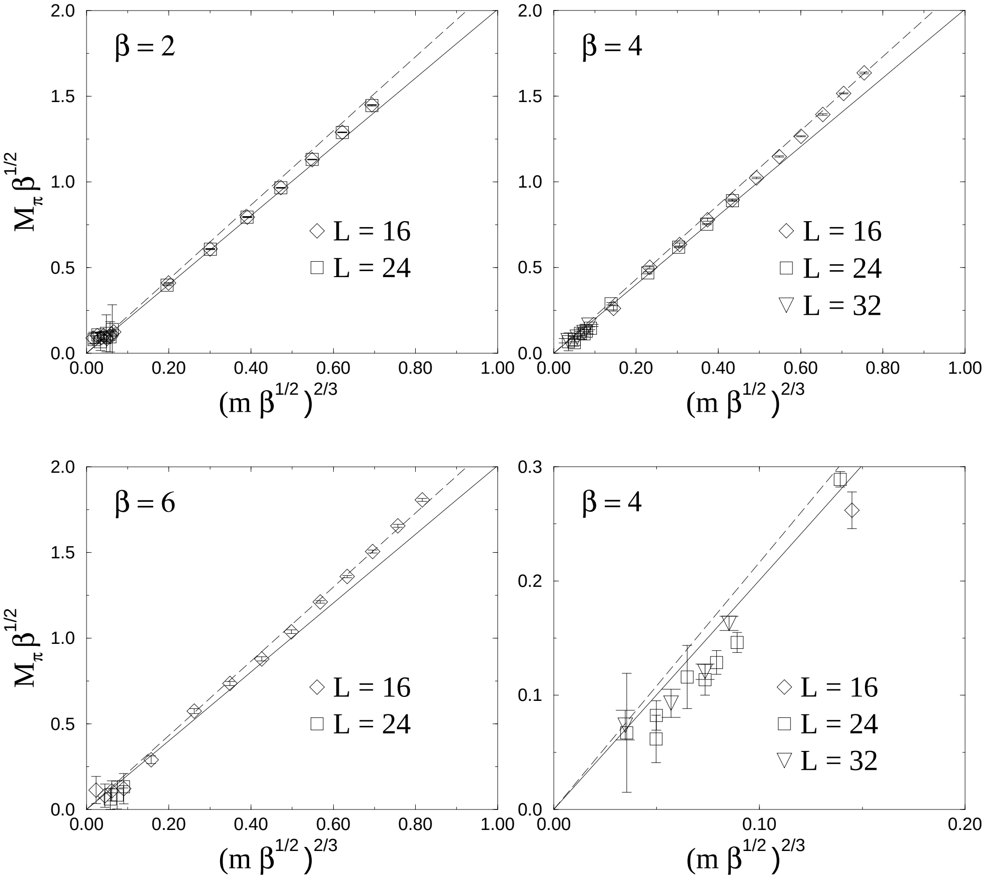

Figure 1: *Results for the pion mass* M_π*. Symbols: Monte Carlo data. Full line: Smilga's formula* (10)*. Dashed line: the semi-classical formula* (7).

In Fig. 2 we show our results for the eta mass M_η at $\beta = 4$ and 6. We find that the data approaches the correct $m = 0$ value (dotted line) as the quark mass vanishes. The approach is smoother as one goes closer to the continuum limit, i.e. increases β. The semi-classical formula (8) provides a reasonable description of the data for larger m, in particular when Smilga's result (10) for M_π is used as an input in (8) (full curve).

For small m the quantum fluctuations become larger and thus the numerical data deviates from the semi-classical curve. This behavior at small m can be fitted by a power law as has been done in [18] for the results from the model with staggered fermions.

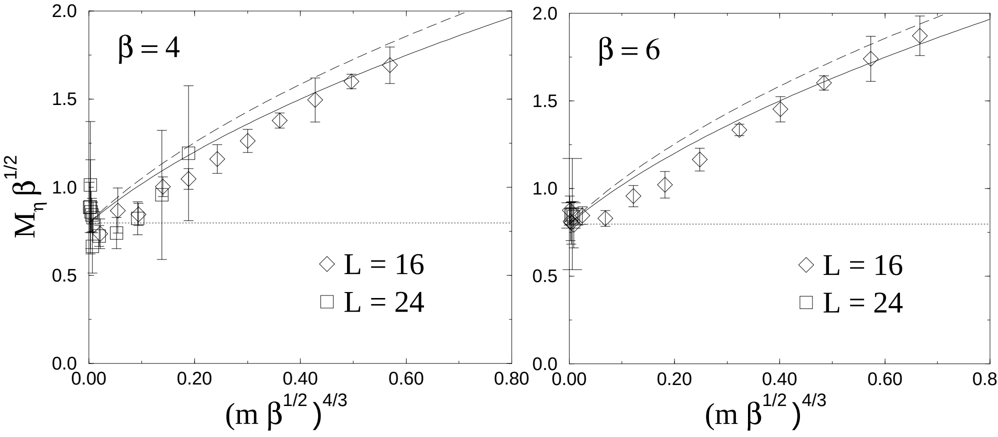

Figure 2: *Results for the eta mass M_η. Symbols: Monte Carlo data. Dashed curve: the semi-classical formula* (8) *with M_π taken from* (7). *Full curve: the semi-classical formula* (8) *with M_π taken from* (10). *The dotted horizontal line corresponds to M_η at quark mass $m = 0$.*

To summarize, we find that the approach to the chiral limit is under good control. As the PCAC quark mass m goes to zero we find that the pion mass M_π vanishes and M_η approaches the Schwinger value $g\sqrt{2/\pi}$. The data for M_π is well described by Smilga's formula (10) for $m \ll g$ with a cross-over to the semi-classical formula (7) as m is increased. For the eta mass M_η the data is reasonably well described by the semi-classical formula (8) with quantum fluctuations becoming less important as the quarks are made heavier.

Acknowledgement: We want to thank Andrei Smilga and Renate Teppner for discussions.
